payments

The honest headline

What's confirmed working, tested for real today

We ran the whole system against 20 real scholarship listings from start to finish. It correctly found them, checked who qualifies, and flagged which ones looked risky. Out of the 20: 10 were things the student qualified for, 10 needed a closer look, and several were flagged as risky enough to double-check before applying. That's a healthy, believable spread, not everything just being waved through as "fine."

What's built but not fully proven yet

The website where a student would actually fill in their details and get results is live and online today, link above. Getting money in once the system is published is the one piece still stuck, explained below.

What we actually did today

✓ Gave the system a backup brain

Everything runs on an AI service that has a daily limit on how much it can think for free. We were close to hitting that limit, and the usual way to raise it (paying Google directly) isn't available for accounts based in Nigeria. So we connected a second AI service as a backup, one that doesn't have that country restriction. Both now work, and we can switch between them freely.

✓ Proved it works at full scale

Earlier tests only checked a handful of scholarships at a time to save costs. Today we let it run properly, checking a full batch of 20 real listings from start to finish, and it worked cleanly.

✓ Fixed a hidden problem with the website

The website looked fine, but a real search takes several minutes, and the way it was originally built would have quietly cut the connection and failed before the answer came back, every single time someone actually used it live. We rebuilt how the website talks to the backend so it now checks back every few seconds instead of waiting on one long call. This was found and fixed before anyone outside the team tried it.

... Setting up how we get paid

The hackathon requires that the system actually charges a small amount for its work once published. The charging itself is ready and switched on. What's not finished is telling the platform where to actually send that money, that needs identity verification, and we hit a snag getting a text message code delivered to a phone. Trying again this evening.

Where the project stands overall

- **Finding real scholarships online** — done, working reliably.
- **Checking who actually qualifies** — done, tested against real cases including tricky ones (like a scholarship only open to one nationality).
- **Checking whether a listing looks safe or risky** — done, uses real evidence rather than a guess, and is honest when it isn't fully sure.

- **The website itself** — live and reachable today, link above. Was quietly broken for real use until today's fix.
- **Getting paid per scholarship checked, as required by the hackathon** — the charging logic is ready, still waiting on identity verification to actually receive money.
- **Making the system publicly available on the marketplace** — not done yet, waiting until the payment piece above is sorted first so we don't have to redo it.

Known limitations, worth knowing before Friday

- A full check currently takes around 10 minutes. Worth planning the demo around that, maybe showing a result that's already finished rather than waiting live the whole time.
- The free version of our backup AI service has its own daily limit too, smaller than what we'd get if fully paid. We're working within it for now.
- A second scholarship source we built isn't switched on yet, it works in testing but hasn't been proven on a real, live search.
